ANALYTICAL INVESTIGATION OF SUPERSONIC TURBOMACHINERY BLADING

I - COMPUTER PROGRAM FOR BLADING DESIGN

by Louis J. Goldman and Vincent J. Scullin

Lewis Research Center

SUMMARY

A FORTRAN IV computer program for the design of supersonic blading based on establishing vortex flow within the blade passage is presented. The method of characteristics, as applied to the two-dimensional isentropic flow of a perfect gas, was utilized for the blade design. The equations necessary for the design are developed. The information required for the program consists of an inlet flow angle, specification of the inlet, outlet, and lower- and upper-circular-surface Mach numbers, and the specific-heat ratio. The program output consists of the blade coordinates and, if desired, a printer plot of the blade profile and flow passage. In addition, supersonic starting and flow separation calculations are performed by the program and obtained as output. An example is included to indicate the use of the program and the results obtainable.

INTRODUCTION

Supersonic compressors and turbines are employed in special circumstances because of their simplicity and low weight. A recent application for a supersonic turbine involves the hydrogen-fueled open-cycle auxiliary space power system described in reference 1. If the highest practical efficiency is to be obtained from supersonic compressors or turbines, proper design methods must be available.

A method for designing supersonic blade sections based on two-dimensional isentropic flow is given in reference 2. The method consists of converting the uniform parallel flow at the blade inlet into a vortex flow field, turning the vortex flow, and re-converting to a uniform parallel flow at the blade exit. The application of this design procedure involves specification of the inlet and outlet Mach numbers, the lower- (or concave) surface Mach number, the upper- (or convex) surface Mach number, the inlet flow

angle, and the specific-heat ratio of the working fluid. In general, a wide range of designs is possible by selection of these parameters. Guidance in the selection of a blade design is obtained by considering blade shape, solidity, and supersonic starting and flow separation problems. In reference 2 the effect of some of the design parameters for low Mach numbers and a specific-heat ratio of 1.4 is examined.

In view of the interest in hydrogen-fueled auxiliary space power systems, an analysis was conducted to gain a better understanding of the effects of the design parameters on the resulting blade geometry and to extend the results of reference 2 to levels of interest for such systems. In reference 3, the effect of surface Mach numbers, inlet flow angle, and specific-heat ratio on the geometric characteristics of supersonic impulse turbine-blade sections is investigated over an inlet Mach number range of 1.5 to 5.0. Blade design limitations resulting from supersonic starting and flow separation problems are also considered. In the present report, a description and a FORTRAN IV listing of a computer program for the design of blading applicable for any supersonic Mach number level and specific-heat ratio are presented. Supersonic starting and flow separation calculations are also performed by the program. An example is included to indicate the use of the program and the results obtainable. The report is organized so that those persons desiring to use the program need only read the sections METHOD OF ANALYSIS, DESCRIPTION OF INPUT, and DESCRIPTION OF OUTPUT. All necessary information pertaining to the program itself is contained in the sections DESCRIPTION OF INPUT, DESCRIPTION OF OUTPUT, and PROGRAM DESCRIPTION.

SYMBOLS

A	area, ft ² (m ²)
a	speed of sound, ft/sec (m/sec)
C	reduction in maximum weight flow due to two-dimensional flow (eq. (34b))
C*	dimensionless blade chord, chord/r*
f(R*)	function defined by eq. (10b)
G*	dimensionless blade spacing, spacing/r*
g _c	dimensional conversion constant, 32.17 ft-lb/(lb)(sec ²) (1 kg-m/(N)(sec ²))
h	blade height, ft (m)
j	index for upper surface of blade
K*	dimensionless vortex constant defined by eq. (23)

K_{\max}^*	value of K^* for which weight flow is maximum
k	index for lower surface of blade
M	Mach number, V/a
M^*	dimensionless velocity or critical velocity ratio, V/V_{cr}
$(M_i^*)_{\max}$	maximum inlet velocity ratio for supersonic starting
$(M_l^*)_{\min}$	minimum lower-surface velocity ratio from separation criterion
$(M_u^*)_{\max}$	maximum upper-surface velocity ratio from separation criterion
m	slope of Mach line
\overline{m}	slope of wall segment
p	static pressure, lb/ft^2 (N/m^2)
$(p_l)_{\max}$	maximum lower-surface static pressure from separation criterion
Q	vortex flow parameter (eq. 34a))
R	radius in vortex field, ft (m)
R^*	dimensionless radius in vortex field, R/r^*
r^*	radius of sonic velocity streamline in vortex field, ft (m)
V	velocity, ft/sec (m/sec)
V_{cr}	critical velocity, ft/sec (m/sec)
w	weight flow, lb/sec (kg/sec)
w_{\max}	maximum weight flow, lb/sec (kg/sec)
X^*	dimensionless X-coordinate of blade (fig. 1), X/r^*
x^*	dimensionless x-coordinate of transition arc (fig. 1), x/r^*
Y^*	dimensionless Y-coordinate of blade (fig. 1), Y/r^*
y^*	dimensionless y-coordinate of transition arc (fig. 1), y/r^*
α	circular arc turning angle, rad
β	flow angle outside blade passage, rad
γ	specific-heat ratio
θ	total flow turning angle, rad
μ	Mach angle, rad

ν	Prandtl-Meyer angle, angle through which flow must turn from Mach 1 to required Mach number, rad
$\Delta\nu$	incremental flow turning, rad
$(\nu_i)_{\max}$	maximum inlet Prandtl-Meyer angle for supersonic starting, rad
$(\nu_l)_{\min}$	minimum lower-surface Prandtl-Meyer angle from separation criterion, rad
$(\nu_u)_{\max}$	maximum upper-surface Prandtl-Meyer angle from separation criterion, rad
ρ	density, lb/ft ³ (kg/m ³)
σ	blade solidity, C^*/G^*
φ	velocity direction angle, rad

Subscripts:

d	downstream of normal shock

k	index for lower surface of blade
l	lower surface of blade
max	maximum
min	minimum
o	blade outlet
u	upper surface of blade

Superscripts:

total-state conditions

METHOD OF ANALYSIS

Blade Description

The design of supersonic blade sections described herein is based on establishing vortex flow within the blade passage by a procedure analogous to that given in reference 2. The blade so designed consists essentially of three major parts: (1) inlet transition arcs, (2) circular arcs, and (3) outlet transition arcs. A typical blade, with pertinent nomenclature noted, is shown schematically in figure 1. The inlet transition arcs

AB	Inlet upper transition arc
FG	Outlet upper transition arc
CD	Inlet lower transition arc
HI	Outlet lower transition arc
AF	Upper circular arc
CH	Lower circular arc
BE and GJ	Straight lines

Figure 1. - Typical supersonic blade section. (All coordinates are made dimensionless by dividing by r^* .)

(lower and upper) are required to convert the assumed uniform parallel flow at the blade inlet into vortex flow. The concentric circular arcs turn and maintain the vortex flow. Finally, the outlet transition arcs reconvert the vortex flow into uniform parallel flow at the blade exit. Straight-line segments parallel to the inlet and outlet flow directions complete the blade profile. Methods for creating a finite thickness at the leading and trailing edges are given in reference 2.

In general, the inlet lower transition arc reduces the Mach number from its value at the blade inlet M_1 to a preselected value of the lower-surface Mach number M_l , whereas the inlet upper transition arc increases the Mach number to a preselected value

Figure 2. - Surface Mach number variation for typical blade section.

of the upper-surface Mach number M_u . The surface Mach numbers remain constant, at these preselected values, on the lower and upper circular arcs. At the outlet region the procedure is reversed. The surface Mach number variation is shown in figure 2 for a typical blade.

The amount of flow turning produced by either the lower or upper surface of the blade consists, in general, of two parts (fig. 1): (1) the turning produced by the transition arcs and (2) the turning produced by the circular arcs. When isentropic flow turning at supersonic speeds is considered, it is convenient to introduce the Prandtl-Meyer angle ν , which is defined as the angle through which the flow must turn from Mach 1 to the required Mach number. The flow turning produced by a transition arc is then equal to differences in Prandtl-Meyer angles and is $\nu_i - \nu_l$ and $\nu_o - \nu_l$ for the inlet and outlet lower transition arcs and $\nu_u - \nu_i$ and $\nu_u - \nu_o$ for the inlet and outlet upper transition arcs, respectively. The turning produced by the inlet or outlet transition arcs cannot exceed the inlet or outlet flow angle β_i or β_o , respectively. The relation between Prandtl-Meyer angle ν and Mach number M is given by the following equations (ref. 4):

$$\nu = \frac{\pi}{4} \left(\sqrt{\frac{\gamma+1}{\gamma-1}} - 1 \right) + \frac{1}{2} \left\{ \sqrt{\frac{\gamma+1}{\gamma-1}} \arcsin \left[(\gamma-1)M^{*2} - \gamma \right] + \arcsin \left(\frac{\gamma+1}{M^{*2}} - \gamma \right) \right\} \quad (1)$$

where the dimensionless velocity or critical velocity ratio M^* is

$$M^* = \left(\frac{\frac{\gamma+1}{2} M^2}{1 + \frac{\gamma-1}{2} M^2} \right)^{1/2} \quad (2)$$

This relation is shown in figure 3 for specific-heat ratios of 1.3, 1.4, and 1.66. As the Mach number approaches infinity, ν approaches an upper limit of $\frac{\pi}{2} \left[\sqrt{(\gamma+1)/(\gamma-1)} - 1 \right]$.

Figure 3. - Variation of Prandtl-Meyer angle with Mach number for different specific-heat ratios.

Blade Design

The method of characteristics as applied to the two-dimensional isentropic flow of a perfect gas is utilized in the design of the supersonic blade sections. A description of the method of characteristics is given in references 4 and 5, and its application to the design of supersonic blade sections is given in references 2 and 6. For purposes of calculation, the flow field is considered to be divided into small regions, in each of which the flow properties are assumed to be constant. If adjacent regions are to differ slightly in properties, then the boundary between the regions must be characteristic lines and can also be shown (ref. 5) to be Mach lines. Therefore, each region is, in general, bounded either by a Mach line or a physical boundary. In figure 4 the flow field for a

Figure 4. - Characteristic network within blade passage.

typical blade passage is divided by characteristic lines into a finite number of regions. The vortex-flow region is bounded by the circular arcs and the outermost vortex characteristics AE and CE. The transition arcs are composed of straight-line segments, and within each region bounded by these segments the flow is constrained to follow the wall direction. The mathematical equations necessary to define the blade are developed in the following sections.

Circular arcs. - Within the concentric circular arcs, vortex flow exists; therefore,

$$VR = \text{Constant} \quad (3)$$

where V is the velocity and R is the radius in the vortex field. In this report, dimensionless parameters are used whenever possible; if this procedure is followed, equation (3) can be rewritten as

$$\left(\frac{V}{V_{cr}}\right)\left(\frac{R}{r^*}\right) = \frac{\text{Constant}}{V_{cr}r^*} \quad (4)$$

where V_{cr} is the critical velocity and r^* is the radius of the sonic velocity streamline in the vortex field. At $R = r^*$, $V = V_{cr}$; therefore, the constant is $V_{cr}r^*$. Equation (4) then becomes

$$M^*R^* = 1 \quad (5)$$

where $M^* = V/V_{cr}$ is the dimensionless velocity and $R^* = R/r^*$ is the dimensionless radius in the vortex field. The Prandtl-Meyer angle ν is related to M^* through equation (1). Therefore, once ν_l and ν_u are specified, M_l^* and M_u^* are fixed, and the circular arc radii R_l^* and R_u^* are determined from equation (5). The amount of lower circular arc turning for the inlet and outlet portions of the blade $\alpha_{l,i}$ and $\alpha_{l,o}$, respectively, are

$$\alpha_{l,i} = \beta_i - (\nu_i - \nu_l) \quad (6a)$$

and

$$\alpha_{l,o} = \beta_o + (\nu_o - \nu_l) \quad (6b)$$

Angles measured in the counterclockwise direction are considered positive. With this convention, the inlet flow angle β_i is positive, and the outlet flow angle β_o is negative. Similarly, for the upper circular arc

$$\alpha_{u,i} = \beta_i - (\nu_u - \nu_i) \quad (7a)$$

and

$$\alpha_{u,o} = \beta_o + (\nu_u - \nu_o) \quad (7b)$$

The circular arcs are completely described by specification of ν_i , ν_o , ν_l , ν_u , and β_i .

The outlet flow angle β_o does not have to be specified because it can be related to M_i , M_o , and β_i from the following consideration.

Because the inlet and outlet blade spacing is the same, the inlet and outlet blade passage areas A_i and A_o , respectively, are related by geometry (see fig. 1) according to the equation

$$\frac{A_i}{A_o} = \frac{\cos \beta_i}{\cos \beta_o} \quad (8)$$

The area ratio A_i/A_o can be obtained from the continuity equation (ref. 5) with the result that equation (8) becomes

$$\beta_o = -\arccos \left\{ \left[\frac{M_i}{M_o} \left(\frac{1 + \frac{\gamma-1}{2} M_o^2}{1 + \frac{\gamma-1}{2} M_i^2} \right)^{(\gamma+1)/2(\gamma-1)} \right] \cos \beta_i \right\} \quad (9)$$

Lower transition arcs. - The lower surface is composed of an inlet and outlet transition arc and a circular arc (fig. 1). For symmetric blades (i. e., $\nu_i = \nu_o$), the two transition arcs are identical, and, therefore, only one needs to be calculated. For asymmetric blades, the two arcs are not identical, one being smaller (less turning) than the other. However, the smaller transition arc corresponds to a portion of the larger arc, and, consequently, only the larger arc need be calculated. If ν_i is greater than ν_o , the inlet transition arc is the larger of the two arcs. For simplicity, the inlet transition arc is assumed to be the larger arc in the following discussion.

In figure 5, the lower transition arc is shown, and the nomenclature used in the computer program is indicated. The calculations are performed with respect to the nondimensional axes x^* and y^* (where the x - and y -coordinates are made dimensionless by dividing by r^*). The transition arc coordinates are generated in a sequential manner (starting at $x^* = 0$, $y^* = R_l^*$) by obtaining the intersection of the straight-line wall segments and straight Mach lines for a specified small change in flow turning. The Mach lines are determined from the outermost or major vortex-expansion characteristic, and the wall segments are determined from the flow direction. After the transition arc coordinates are calculated, they are rotated through an angle of $\alpha_{l,i}$ to obtain the coordinates of interest in the blade design (see fig. 1).

For the vortex region, it can be shown (ref. 2) that the velocity direction ϕ and the dimensionless radius R^* are related along the characteristic line by the equation

Figure 5. - Nomenclature used for calculation of inlet lower transition arc.

$$\varphi = \pm \frac{1}{2} f(R^*) + \text{Constant} \quad (10a)$$

where

$$f(R^*) = \sqrt{\frac{\gamma+1}{\gamma-1}} \arcsin\left(\frac{\gamma-1}{R^{*2}} - \gamma\right) + \arcsin\left[(\gamma+1)R^{*2} - \gamma\right] \quad (10b)$$

Two families of characteristics exist: the positive sign in equation (10a) gives the expansion lines, and the negative sign gives the compression lines. The major vortex-expansion-characteristic equation is

$$\varphi = \frac{1}{2} [f(R^*) - f(R_l^*)] \quad (11)$$

since the boundary condition at $x^* = 0$ is that $\varphi = 0$ and $R^* = R_l^*$. If the flow field is divided into small regions, the flow direction at any point along the characteristic line (as given by eq. (11)) may be considered to be equal to the flow direction within the adjacent flow region, as indicated in figure 5. For k transition arc segments, each of which produces $\Delta\nu$ degrees of turning, the flow direction within any flow segment $\varphi_{k,i}$ is given by

$$\varphi_{k,i} = \nu_i - \nu_l - (k-1)\Delta\nu = \varphi_{k+1,i} + \Delta\nu \quad (12)$$

where k is an integer that varies from 1 to $\left[(\nu_i - \nu_l)/\Delta\nu\right] + 1$. At $k = \left[(\nu_i - \nu_l)/\Delta\nu\right] + 1$, the flow direction is 0, and at $k = 1$, it is $\nu_i - \nu_l$. Equating equations (11) and (12) and eliminating $f(R_l^*)$ through equations (1), (5), and (10b) result in

$$f(R_{k,i}^*) = 2\nu_i - \frac{\pi}{2} \left(\sqrt{\frac{\gamma+1}{\gamma-1}} - 1 \right) - 2(k-1)\Delta\nu \quad (13)$$

which relates the dimensionless radius R^* to the incremental flow turning $\Delta\nu$ along the major vortex-expansion characteristic. At $k = \left[(\nu_i - \nu_l)/\Delta\nu\right] + 1$, $R_{k,i}^* = R_l^*$; as k is decreased, $R_{k,i}^*$ decreases and is obtained by the simultaneous solution of equations (10b) and (13) by an iterative procedure. Since $R_{k,i}^*$ can be determined for any value of k , the x^*, y^* coordinates along the major expansion characteristic can be obtained from

$$x_{k,i}^* = -R_{k,i}^* \sin \varphi_{k,i} \quad (14a)$$

and

$$y_{k,i}^* = R_{k,i}^* \cos \varphi_{k,i} \quad (14b)$$

These coordinates are also points on the straight Mach lines. The equation specifying the Mach line is therefore determined once the slope is obtained, which is easily accomplished because the Mach line is inclined at the Mach angle μ to the velocity direction (see fig. 5). The Mach line, therefore, makes an angle of $\varphi + \mu$ with respect to the x^* axis. It is possible to define the Mach line at the mean Mach angle to the mean flow direction (ref. 5) so that the slope of the Mach line $m_{k,i}$ is given by

$$m_{k,i} = \tan \left(\frac{\varphi_{k,i} + \varphi_{k+1,i}}{2} + \frac{\mu_{k,i} + \mu_{k+1,i}}{2} \right) \quad (15a)$$

where

$$\mu_{k,i} = -\arcsin \left(\frac{1}{M_{k,i}} \right) = -\arcsin \left[\sqrt{\left(\frac{\gamma + 1}{2} \right) R_{k,i}^{*2} - \left(\frac{\gamma - 1}{2} \right)} \right] \quad (15b)$$

The equation of the Mach line is therefore

$$y^* = m_{k,i}(x^* - x_{k,i}^*) + y_{k,i}^* \quad (16)$$

where k varies from 1 to $k_{\max} = (\nu_i - \nu_l)/\Delta\nu$. The equation of the transition arc segment is more easily determined since each segment is a straight line parallel to the velocity direction φ . The slope of the wall segment $\overline{m}_{k,i}$ is then

$$\overline{m}_{k,i} = \tan \varphi_{k+1,i} \quad (17)$$

and the equation for the wall segment is

$$y^* = \overline{m}_{k,i} \left[x^* - (x_l^*)_{k+1,i} \right] + (y_l^*)_{k+1,i} \quad (18)$$

where k varies from 1 to k_{\max} and x_l^* and y_l^* are the lower transition arc coordinates. The values of x_l^* and y_l^* are known at $k = (\nu_i - \nu_l)/\Delta\nu + 1 = k_{\max} + 1$, where $x_l^* = 0$ and $y_l^* = R_l^*$. The remaining transition coordinates are generated by finding the intersection of the Mach lines with the wall segments starting at $k = k_{\max}$ and sequentially decreasing k until $k = 1$. The intersection of the two straight lines is given by

$$(x_l^*)_{k,i} = \frac{\left[(y_l^*)_{k+1,i} - \bar{m}_{k,i}(x_l^*)_{k+1,i} \right] - (y_{k,i}^* - m_{k,i}x_{k,i}^*)}{m_{k,i} - \bar{m}_{k,i}} \quad (19a)$$

and

$$(y_l^*)_{k,i} = \frac{m_{k,i} \left[(y_l^*)_{k+1,i} - \bar{m}_{k,i}(x_l^*)_{k+1,i} \right] - \bar{m}_{k,i}(y_{k,i}^* - m_{k,i}x_{k,i}^*)}{m_{k,i} - \bar{m}_{k,i}} \quad (19b)$$

The transition arc coordinates obtained from equation (19) are rotated through an angle $\alpha_{l,i}$ resulting in the X^*, Y^* coordinates of interest in the blade design. The rotated coordinates X_l^* and Y_l^* are obtained from

$$(X_l^*)_{k,i} = (x_l^*)_{k,i} \cos \alpha_{l,i} - (y_l^*)_{k,i} \sin \alpha_{l,i} \quad (20a)$$

and

$$(Y_l^*)_{k,i} = (x_l^*)_{k,i} \sin \alpha_{l,i} + (y_l^*)_{k,i} \cos \alpha_{l,i} \quad (20b)$$

Upper transition arcs. - The upper surface (like the lower surface) is composed, in part, of an inlet and outlet transition arc, only one of which must be calculated. For simplicity, it is again assumed that the inlet transition arc is the larger of the two arcs. (For the upper arc, this requires that ν_o be greater than ν_i .) The upper transition arc is shown schematically in figure 6, and the pertinent nomenclature is noted. The procedure employed to calculate the upper transition arc is analogous to that used for the lower transition arc; the resulting equations which are of similar form are not repeated herein. The subscript j is used to represent the upper transition arc coordinates where j varies from 1 to $j_{\max} = (\nu_u - \nu_i)/\Delta\nu$.

Geometric parameters. - After the blade calculations have been performed, a number of blade parameters of interest, including blade solidity, spacing, chord, and total

Figure 6. - Nomenclature used for calculation of inlet upper transition arc.

flow turning angle, are calculated. The blade spacing G^* and chord C^* are obtained from the blade coordinates, and the solidity is obtained from the ratio C^*/G^* . The total flow turning angle θ is obtained from the inlet and outlet flow angles. The blade coordinates are also translated by G^* so that coordinates for two complete blades are obtained.

Design Limitations

The design limitations (i. e., the constraints on the choice of ν_l and ν_u for specified ν_i , ν_o , β_i , and γ) imposed by consideration of supersonic starting and flow separation problems have been discussed in reference 3. These limitations are calculated by the procedure described in the following paragraphs and are given as output from the computer program presented herein.

Supersonic starting. - The problem of establishing supersonic flow on startup is discussed in reference 7 for supersonic compressors. For supersonic turbines, the resulting design limitations due to starting are presented in reference 2, where it is assumed that a normal shock wave spans the blade inlet at the instant of startup. Under this condition it is necessary to ensure that the weight flow can pass through the turbine. The maximum value of the inlet Prandtl-Meyer angle $(\nu_i)_{\max}$ is determined by first finding the maximum weight flow through the blade passage, while taking into account the normal shock losses. This maximum weight flow is then equated to the flow rate after the shock has passed through the passage.

The weight flow through the passage is obtained by integrating the continuity equation in the vortex region

$$w = h \int_{R_u}^{R_l} \rho V dR \quad (21)$$

where ρ is the density, V is the velocity, and h is the blade height. The density can be written as (ref. 2)

$$\rho = \rho'_{i,d} \left[1 - \left(\frac{\gamma - 1}{2} \right) \left(\frac{V}{a'_{i,d}} \right)^2 \right]^{1/(\gamma-1)} \quad (22)$$

where $\rho'_{i,d}$ and $a'_{i,d}$ are the density and the speed of sound, respectively, just downstream of the shock, and are evaluated at total conditions. For perfect gases, the total

temperature is constant through a normal shock so that $a'_{i,d} = a'_i$. Utilizing equation (3) and the definition

$$K^* = \sqrt{\frac{\gamma - 1}{2}} \left(\frac{VR}{a'_i R_l} \right) \quad (23)$$

results in equation (21) in the following form:

$$w = ha'_i \rho'_{i,d} R_l \sqrt{\frac{2}{\gamma - 1}} \int_{R_u}^{R_l} \left(1 - \frac{K^{*2} R_l^2}{R^2} \right)^{1/(\gamma-1)} \frac{K^*}{R} dR \quad (24)$$

Differentiating equation (24) with respect to K^* and setting the result equal to 0 give the value of K^* (denoted as K^*_{\max}) for which the weight flow is a maximum. This procedure gives

$$\begin{aligned} \frac{dw}{dK^*} = ha'_i \rho'_{i,d} R_l \sqrt{\frac{2}{\gamma - 1}} \int_{R_u}^{R_l} \left[\left(1 - \frac{K_{\max}^{*2} R_l^2}{R^2} \right)^{1/(\gamma-1)} \right. \\ \left. - \frac{2}{\gamma - 1} \left(\frac{K_{\max}^* R_l}{R} \right)^2 \left(1 - \frac{K_{\max}^{*2} R_l^2}{R^2} \right)^{(2-\gamma)/(\gamma-1)} \right] \frac{dR}{R} \equiv 0 \quad (25) \end{aligned}$$

Changing the variable from R to M^* gives, for equation (25),

$$\begin{aligned}
& \int_{M_l^*}^{M_u^*} \left[1 - \left(\frac{K_{\max}^*}{M_l^*} \right)^2 M^{*2} \right]^{1/(\gamma-1)} \frac{dM^*}{M^*} \\
&= \frac{2}{\gamma-1} \int_{M_l^*}^{M_u^*} \left(\frac{K_{\max}^*}{M_l^*} \right)^2 \left[1 - \left(\frac{K_{\max}^*}{M_l^*} \right)^2 M^{*2} \right]^{(2-\gamma)/(\gamma-1)} M^* dM^* \quad (26)
\end{aligned}$$

Integrating the right side of equation (26) results in

$$\int_{M_l^*}^{M_u^*} \left[1 - \left(\frac{K_{\max}^*}{M_l^*} \right)^2 M^{*2} \right]^{1/(\gamma-1)} \frac{dM^*}{M^*} = \left(1 - K_{\max}^{*2} \right)^{1/(\gamma-1)} - \left[1 - K_{\max}^{*2} \left(\frac{M_u^*}{M_l^*} \right)^2 \right]^{1/(\gamma-1)} \quad (27)$$

Similarly, equation (24) in terms of M^* becomes

$$w_{\max} = r^* h a_{i,d}^* \rho_{i,d}^* \sqrt{\frac{2}{\gamma-1}} \int_{M_l^*}^{M_u^*} \frac{K_{\max}^*}{M_l^*} \left[1 - \left(\frac{K_{\max}^*}{M_l^*} \right)^2 M^{*2} \right]^{1/(\gamma-1)} \frac{dM^*}{M^*} \quad (28)$$

The value of K_{\max}^* is determined from equation (27) by an iterative procedure (for given values of M_l^* and M_u^*), and then the maximum weight flow is obtained from equation (28). After the shock has passed through the turbine, the weight flow can again be obtained from equation (21), which is rewritten by substituting $VR = V_{cr} r^*$ and changing the variable from R to M^* to give

$$w = r^* h \int_{M_l^*}^{M_u^*} \rho V_{cr} \frac{dM^*}{M^*} \quad (29)$$

Substituting the following relations (ref. 5) into equation (29)

$$\rho = \rho'_i \left(\frac{2}{\gamma + 1} \right)^{1/(\gamma-1)} \left(\frac{\gamma + 1}{2} - \frac{\gamma - 1}{2} M^{*2} \right)^{1/(\gamma-1)} \quad (30)$$

and

$$V_{cr} = a'_i \sqrt{\frac{2}{\gamma + 1}} \quad (31)$$

gives

$$w = r^* h a'_i \rho'_i \sqrt{\frac{2}{\gamma + 1}} \left(\frac{2}{\gamma + 1} \right)^{1/(\gamma-1)} \int_{M_l^*}^{M_u^*} \left(\frac{\gamma + 1}{2} - \frac{\gamma - 1}{2} M^{*2} \right)^{1/(\gamma-1)} \frac{dM^*}{M^*} \quad (32)$$

where the term multiplying $r^* h a'_i \rho'_i$ is defined as the weight-flow parameter. Equating the two weight flows, equations (28) and (32), results in

$$\frac{Q}{1 - C} = \frac{\rho'_{i,d}}{\rho'_i} = \frac{p'_{i,d}}{p'_i} \quad (33)$$

where

$$Q = \frac{M_l^* M_u^*}{M_u^* - M_l^*} \int_{M_l^*}^{M_u^*} \left(\frac{\gamma + 1}{2} - \frac{\gamma - 1}{2} M^{*2} \right)^{1/(\gamma-1)} \frac{dM^*}{M^*} \quad (34a)$$

and

$$C = 1 - \sqrt{\frac{\gamma + 1}{\gamma - 1}} \left(\frac{\gamma + 1}{2} \right)^{1/(\gamma-1)} \left(\frac{M_u^*}{M_u^* - M_l^*} \right) \int_{M_l^*}^{M_u^*} K_{\max}^* \left[1 - \left(\frac{K_{\max}^*}{M_l^*} \right)^2 M^{*2} \right]^{1/(\gamma-1)} \frac{dM^*}{M^*} \quad (34b)$$

The parameter C has been shown in reference 2 to be the reduction in maximum flow rate caused by two-dimensional flow. The quantity $p'_{i,d}/p'_i$ is the total pressure recovery for a normal shock and is given by (ref. 5)

$$\frac{p'_{i,d}}{p'_i} = (M_i^*)_{\max}^{2\gamma/(\gamma-1)} \left[\frac{1 - \left(\frac{\gamma-1}{\gamma+1} \right) (M_i^*)_{\max}^2}{(M_i^*)_{\max}^2 - \frac{\gamma-1}{\gamma+1}} \right]^{1/(\gamma-1)} \quad (35)$$

The maximum inlet velocity ratio $(M_i^*)_{\max}$ is obtained (for given values of M_l^* and M_u^*) by simultaneous solution of equations (33) and (35), by using the definition in equations (34a) and (34b), and by obtaining K_{\max}^* from equation (27). The maximum inlet Prandtl-Meyer angle for supersonic starting $(\nu_i)_{\max}$ is then obtained from equation (1).

Flow separation. - Analysis of supersonic blade sections (ref. 3) has shown the desirability of maintaining high surface Mach numbers to alleviate the problem of supersonic starting. Under these conditions, however, adverse pressure gradients created on the blade surfaces would be expected to cause flow separation and, consequently, poor performance. Experimental investigation of simple shapes with incompressible flow at fairly high pressure gradients (ref. 8) has indicated that if the coefficient of pressure recovery (defined as the ratio of the pressure rise to the dynamic pressure at the initial point) is less than about 1/2, flow separation may be avoided. This criterion was used in the analysis presented in reference 3 to give some indication of the design restrictions due to flow separation. For supersonic velocities the separation value of the coefficient of pressure recovery may be less than 1/2. The calculational procedure is as follows.

Flow separation can occur on both the lower and upper surfaces of the blade, but since the calculational procedure is similar for both cases only the derivation for the lower surface is presented. The flow separation criterion can be written as

$$\frac{(p_l)_{\max} - p_i}{\frac{\rho_i V_i^2}{2g_c}} = \frac{1}{2} \quad (36)$$

where $(p_l)_{\max}$ is the maximum lower-surface pressure possible (for given inlet conditions) without causing separation. Equation (36) can be rewritten in the form

$$\frac{(p_l)_{\max}}{p_i'} = \frac{p_i}{p_i'} \left[1 + \frac{1}{2} \left(\frac{\frac{1}{2g_c} \rho_i V_i^2}{p_i} \right) \right] \quad (37)$$

where the equation has been divided by the inlet total pressure p_i' . Substituting the following relations (ref. 9) into equation (37)

$$\frac{p}{p'} = \left(1 - \frac{\gamma - 1}{\gamma + 1} M^{*2} \right)^{\gamma/(\gamma-1)} \quad (38a)$$

and

$$\frac{\frac{1}{2g_c} \rho V^2}{p} = \frac{\frac{\gamma}{\gamma + 1} M^{*2}}{1 - \frac{\gamma - 1}{\gamma + 1} M^{*2}} \quad (38b)$$

and simplifying result in

$$(M_l^*)_{\min} = \sqrt{\frac{\gamma + 1}{\gamma - 1}} \left\{ 1 - \left(1 - \frac{\gamma - 1}{\gamma + 1} M_i^{*2} \right) \left[1 + \frac{1}{2} \left(\frac{\frac{\gamma}{\gamma + 1} M_i^{*2}}{1 - \frac{\gamma - 1}{\gamma + 1} M_i^{*2}} \right) \right]^{(\gamma-1)/\gamma} \right\}^{1/2} \quad (39)$$

Similarly, applying the same criterion to the upper surfaces gives

$$M_o^* = \sqrt{\frac{\gamma + 1}{\gamma - 1}} \left\{ 1 - \left[1 - \frac{\gamma - 1}{\gamma + 1} (M_u^*)_{\max}^2 \right] \left[1 + \frac{1}{2} \left(\frac{\frac{\gamma}{\gamma + 1} (M_u^*)_{\max}^2}{1 - \frac{\gamma - 1}{\gamma + 1} (M_u^*)_{\max}^2} \right) \right]^{(\gamma-1)/\gamma} \right\}^{1/2} \quad (40)$$

The corresponding Prandtl-Meyer angles $(\nu_l)_{\min}$ and $(\nu_u)_{\max}$ are obtained from equation (1).

03-6729

DESCRIPTION OF INPUT

The input for the computer program consists of an inlet flow angle, several Prandtl-Meyer angles, the specific-heat ratio γ , and an angular increment. In addition, three optional switches must be set which regulate the content and form of the output. All the input parameters, except γ and the switches, must be specified in degrees. The input variables are as follows:

BETAN	inlet flow angle, β_i
DELV	flow turning increment (recommended value, 0.1), $\Delta\nu$
GAM	specific-heat ratio, γ
IPRINT	a value of 0 will result in printing of rotated blade coordinates X^* and Y^* ; a value of 1 will cause both rotated and unrotated coordinates X^* , Y^* and x^* , y^* (see fig. 1) to be printed
ISTART	a value of 0 will cause both starting and blade design calculations to be printed out; a value of 1 will cause only starting calculations to be performed and printed out
NPLOT	a value of 0 will cause blade profile and flow passage to be plotted; a value of 1 will suppress the plot
VIN	inlet Prandtl-Meyer angle, ν_i
VLOW	lower-surface Prandtl-Meyer angle, ν_l
VOUT	outlet Prandtl-Meyer angle, ν_o
VUP	upper-surface Prandtl-Meyer angle, ν_u

The flow turning increment $\Delta\nu$ must be specified so that $(\nu_i - \nu_l)/\Delta\nu$, $(\nu_o - \nu_l)/\Delta\nu$, $(\nu_u - \nu_i)/\Delta\nu$, and $(\nu_u - \nu_o)/\Delta\nu$ are all integers. Table I shows a sample input card.

DESCRIPTION OF OUTPUT

An example of the output obtained from the program is shown in table II. The output corresponds to the input data shown in table I and consists of tables of coordinates for the description of two blade sections, supersonic starting and flow separation parameters, and a plot of the blade profile and flow passage. This example required approximately 0.2 minute of computer running time. Each section of the output has been numbered to correspond to the following description:

- (1) The first output of the program is a listing of the supersonic starting parameters.

If ISTART=0, the program will continue with the blade design calculations. If ISTART=1, no further output is obtained.

(2) The next output is a listing of all the input data plus the value of the calculated outlet flow angle.

(3) If IPRINT=1, the following tables are printed:

- (a) Unrotated coordinates of the lower- and upper-surface transition arcs
- (b) Coordinates of the lower- and upper-surface circular arcs
- (c) Coordinates of the upper-surface straight-line segments

This output is, in general, not of interest except for debugging purposes and may be omitted by setting IPRINT=0.

(4) The next output is tables of the rotated coordinates of the lower and upper transition arcs. In addition, these coordinates are translated by the value of the blade spacing so that coordinates for two blade sections are obtained. Every tenth calculation point is printed if $\Delta\nu < 0.2^\circ$; otherwise every calculation point is printed.

(5) The next output is a listing of miscellaneous parameters including

- (a) Inlet, outlet, and surface dimensionless velocities or critical velocity ratios and Mach numbers
- (b) Dimensionless blade spacing, chord and solidity
- (c) Separation limitation for the lower- and upper-surface Prandtl-Meyer angles

(6) If NPLOT=0, the final output is a printer plot of the blade profile and the flow passage. If NPLOT=1, this output is omitted.

PROGRAM DESCRIPTION

Main Program

The main program generates a table of the inlet and outlet transition arcs of the upper, lower, and translated curves. It also computes several parameters which are pertinent to the blade description, such as Mach numbers and radii, and, as an option, plots a blade profile and flow channel. The plotting is done by subroutine PLOTMY, (ref. 10). The program variables are

ALPH	fixed angle
ALPHLN	rotation angle for lower-curve inlet transition arc, $\alpha_{l,i}$
ALPHLO	rotation angle for lower-curve outlet transition arc, $\alpha_{l,o}$
ALPHUI	rotation angle for upper-curve inlet transition arc, $\alpha_{u,i}$
ALPHUO	rotation angle for upper-curve outlet transition arc, $\alpha_{u,o}$
ALPHUP	temporary storage
ALPLOW	temporary storage
ANGLE	logical switch
BETAN	see INPUT
BETAT	outlet flow angle, β_o
CONVER	conversion factor for degrees to radians
COSALN	cosine of ALPHLN
COSALO	cosine of ALPHLO
COSAUI	cosine of ALPHUI
COSAUI	cosine of ALPHUI
COSAUI	cosine of ALPHUI
COSAUI	cosine of ALPHUI
COSAUI	cosine of ALPHUI
COSAUI	cosine of ALPHUI
COSAUI	cosine of ALPHUI
CSTAR	blade chord, C^*
DALPH	angle increment
DELF	see subroutine ROOT
DELV	see INPUT
DELXI	1/15 length of straight-line portion of upper-curve inlet arc
DELXO	1/15 length of straight-line portion of upper-curve outlet arc
EMJ	slope of Mach lines, m_j

EMK	slope of Mach lines (eq. (15)), m_k
EMWJ	slope of wall segments, \bar{m}_j
EMWK	slope of wall segments (eq. (17)), \bar{m}_k
F(V, FN)	internally defined function (eq. (13)), $f(R^*)$
FLO	see subroutine START
FN	floating point index
FOFX	see subroutine ROOT
FUP	see subroutine START
GAM	ratio of specific heats, γ
GAMEXP	$1/(GAM - 1)$
GAMM1	$(GAM - 1)/2$
GAMP1	$(GAM + 1)/2$
GRTY	dummy name
GSTAR	blade spacing, G^*
I	counter
IPRINT	see INPUT
ISTART	see INPUT
J	variable index for upper curve
JJ	variable index
JDEX	variable index
JMAXN	number of points on upper-curve inlet transition arc
JMAXO	number of points on upper-curve outlet transition arc
JMN	maximum of JMAXO and JMAXN
JN	variable index
JNDEX	number of upper-curve transition arc points to be printed
JNN	variable index
JO	variable index
JOO	variable index
K	variable index for lower curve

KK	variable index
KKK	array required by PLOTMY (see ref. 10)
KDEX	variable index
KMAXN	number of points on lower-curve inlet transition arc
KMAXO	number of points on lower-curve outlet transition arc
KMN	maximum of KMAXN and KMAXO
KN	variable index
KNDEX	number of lower-curve transition arc points to be printed
KNN	variable index
KO	variable index
KOO	variable index
KOUNT	counter
L	counter
LLL	NP1 + NP2
LSTORE	number of points saved per 5° of turning
LSTR	temporary storage
M	counter
MAXN	integer constant
MAXO	integer constant
N	variable index
NPER	variable governing selective storage
NPLOT	see INPUT
NP1	number of points on lower curve which have been saved for plotter
NP2	number of points on translated lower curve which have been saved for plotter
NP3	number of points on upper curve which have been saved for plotter
NSUM	total number of points which have been stored for plotter
NUM	counter
P	array required by PLOTMY (see ref. 10)
PERM	$[(\text{GAM} + 1)/(\text{GAM} - 1)]^{1/2}$

PHIJ	flow direction, φ_j
PHIJP1	previous value of PHIJ, φ_{j+1}
PHIK	flow direction (eq. (12)), φ_k
PHIKP1	previous value of PHIK, φ_{k+1}
R	array for storing radii of major vortex-compression-characteristic points, R_j^*
RA	array for storing radii of major vortex-expansion-characteristic points, R_k^*
RECONV	conversion factor for radians to degrees
RIN	1/SSMIN
RLOW	radius of circular arc of lower curve as calculated in JOKOS, R_l^*
ROUT	1/SSMOUT
RUP	radius of upper-curve circular arc, R_u^*
SAME	see subroutine START
SIGMA	blade solidity, σ
SINALN	sine of ALPHLN
SINALO	sine of ALPHLO
SINAUI	sine of ALPHUI
SINAUO	sine of ALPHUO
SM	temporary storage for Mach numbers, M
SMIN	inlet Mach number, M_i
SMLOW	lower-surface Mach number, M_l
SMOUT	outlet Mach number, M_o
SMS	temporary storage for velocity ratio, M^*
SMUP	upper-surface Mach number, M_u
SSMIN	inlet velocity ratio, M_i^*
SSMLow	lower-surface velocity ratio, M_l^*
SSMOUT	outlet velocity ratio, M_o^*
SSMUP	upper-surface velocity ratio, M_u^*
TANBI	tangent of BETAN
TANBO	tangent of BETAT

TEMP	temporary storage
TEMPP	temporary storage
TEMPPP	temporary storage
THETA	total flow turning angle, θ
TR	temporary storage for radii
TX	temporary storage for unrotated x*-coordinates
TXLO	temporary storage for values of XLOW(I)
TXUP	temporary storage for values of XUP(I)
TY	temporary storage for unrotated y*-coordinates
TYLO	temporary storage for values of YLOW(I)
TYUP	temporary storage for values of YUP(I)
UMJ	Mach angle, μ_j
UMJP1	previous value of UMJ, μ_{j+1}
UMK	Mach angle (eq. (15)), μ_k
UMKP1	previous value of UMK, μ_{k+1}
V	temporary storage for Prandtl-Meyer angles, ν
VIMAX	see subroutine START
VIN	see INPUT
VLOW	see INPUT
VLSPMN	minimum lower-surface Prandtl-Meyer angle from separation criterion, $(\nu_l)_{\min}$
VNL	VIN-VLOW
VOL	VOUT-VLOW
VOUT	see INPUT
VUI	VUP-VIN
VUMAX	$\frac{\pi}{2} \left(\sqrt{\frac{\gamma+1}{\gamma-1}} - 1 \right)$
VUP	see INPUT

VUSPMX	maximum upper-surface Prandtl-Meyer angle from separation criterion, $(\nu_u)_{\max}$
VUT	VUP-VOUT
X0	see subroutine ROOT
X1	see subroutine ROOT
X2	see subroutine ROOT
XCG	X*-coordinate of a translated-curve circular arc point
XCLOW	X*-coordinate of a lower-curve circular arc point
XCUP	X*-coordinate of an upper-curve circular arc point
XDOWN	array for storing X*-coordinate of points to be plotted
XINTL	see subroutine ROOT
XLOW	array for storing x*-coordinate of unrotated lower transition arc points, $(x_l^*)_k$
XLOWN	array for storing X*-coordinate of lower-curve rotated inlet transition arc points, $(X_l^*)_{k,i}$
XLOWO	array for storing X*-coordinate of lower-curve rotated outlet transition arc points, $(X_l^*)_{k,o}$
XMLOW	temporary storage for values of -XLOW(I)
XMUP	temporary storage for values of -XUP(I)
XSIN	X*-coordinate of a point on inlet straight-line portion of upper curve
XSOUT	X*-coordinate of a point on outlet straight-line portion of upper curve
XUP	array for storing x*-coordinate of unrotated upper transition arc points, $(x_u^*)_j$
XUPN	array for storing X*-coordinate of upper-curve rotated inlet transition arc points, $(X_u^*)_{j,i}$
XUPO	array for storing X*-coordinate of upper-curve rotated outlet transition arc points, $(X_u^*)_{j,o}$
YACRS1	array for storing Y*-coordinates of points for plotter
YACRS2	array for temporary storage of Y*-coordinate of translated lower-curve points for plotter

YCG	Y*-coordinate of a translated-curve circular arc point
YCLOW	Y*-coordinate of a lower-curve circular arc point
YCUP	Y*-coordinate of an upper-curve circular arc point
YLASTI	Y*-coordinate of first point on inlet side of upper curve
YLASTO	Y*-coordinate of first point on outlet side of upper curve
YLOW	array for storing y*-coordinate of unrotated lower transition arc points, $(y_l^*)_k$
YLOWN	array for storing Y*-coordinate of lower-curve rotated inlet transition arc points, $(Y_l^*)_{k,i}$
YLOWO	array for storing Y*-coordinate of lower-curve rotated outlet transition arc points, $(Y_l^*)_{k,o}$
YNG	temporary storage for Y*-coordinate of a point on translated-curve inlet transition arc
YSIN	Y*-coordinate of a point on inlet straight-line portion of upper curve
YSNG	Y*-coordinate of a point on inlet straight-line portion of translated upper curve
YSOUT	Y*-coordinate of a point on outlet straight-line portion of upper curve
YSTG	Y*-coordinate of a point on outlet straight-line portion of translated upper curve
YTG	temporary storage for Y*-coordinate of a point on translated-curve outlet transition arc
YUP	array for storing y*-coordinate of unrotated upper transition arc points, $(y_u^*)_j$
YUPN	array for storing Y*-coordinate of upper-curve rotated inlet transition arc points, $(Y_u^*)_{j,i}$
YUPO	array for storing Y*-coordinate of upper-curve rotated outlet transition arc points, $(Y_u^*)_{j,o}$

Subroutine ROOT

Subroutine ROOT is a general routine for finding the roots of equations and is derived from the "half-interval search" method described in reference 11. This method

depends on successively halving an interval which is known to contain the desired root. Subroutine ROOT is used to calculate R^* from equation (10b).

A call to ROOT has the form CALL ROOT (X0, X2, XINTL, FOFX, FUNC, X1), where the elements of the call vector are

X0 lower bound of initial root interval
X2 upper bound of initial root interval
XINTL initial estimate of value of root
FOFX given value of dependent variable
FUNC externally defined function
X1 value of root

Other program variables are

A FOFX-F2
DELF convergence criterion
F0 function FUNC evaluated at XX0
F2 function FUNC evaluated at XX2
FX function FUNC evaluated at X
KOUNT count of number of iterations performed
X temporary storage for present estimate of root
XX0 present value of lower bound of root interval
XX2 present value of upper bound of root interval

Subroutine START

Subroutine START is used to compute the maximum value of the inlet Prandtl-Meyer angle $(\nu_i)_{\max}$ for supersonic starting for various lower- and upper-surface Prandtl-Meyer angles. Several other parameters of interest are computed by START and are printed as output. Among these parameters are the vortex constant for maximum weight flow K_{\max}^* , the reduction in weight flow due to two-dimensional flow C, and the maximum value of the inlet velocity ratio for supersonic starting $(M_i^*)_{\max}$.

A call to START has the form CALL START (VLOW, FLO, VUP, FUP, VIMAX), where the elements of the call vector are

VLOW lower-surface Prandtl-Meyer angle, ν_l

FLO eq. (10b) evaluated at R_l^*
 VUP upper-surface Prandtl-Meyer angle, ν_u
 FUP eq. (10b) evaluated at R_u^*
 VIMAX maximum inlet Prandtl-Meyer angle for supersonic starting, $(\nu_1)_{\max}$
 Other program variables are
 BINTGR value of integral (eq. (27b))
 C reduction in maximum weight flow due to two-dimensional flow (eq. (34b))
 CINTGR value of integral (eq. (32))
 FINTL eq. (27) evaluated at $K_{\max}^* = XINTL$
 F0 eq. (27) evaluated at $K_{\max}^* = X0$
 F2 eq. (27) evaluated at $K_{\max}^* = X2$
 FOFX eq. (27) evaluated at $K_{\max}^* = XAMK$
 Q eq. (34a)
 RATIO ratio of Q to $1 - C$
 RLOW radius of circular portion of lower curve, R_l^*
 RUP radius of circular portion of upper curve, R_u^*
 SAME square of ratio of XAMK to SSMIOW
 SLOPE slope of line
 SSMIAX maximum value of entering velocity ratio for starting, $(M_1^*)_{\max}$
 SSMLOW lower-surface velocity ratio, M_l^*
 SSMUP upper-surface velocity ratio, M_u^*
 WSTAR weight-flow parameter (eq. (32))
 XAMK vortex constant for maximum weight flow, K_{\max}^*
 XINTL initial estimate of a parameter
 X0 lower bound of a parameter
 X2 upper bound of a parameter
 YINCPT y-intercept of a line

Subroutine MSSTAR

Subroutine MSSTAR is used to determine the minimum lower-surface Prandtl-Meyer angle and the maximum upper-surface Prandtl-Meyer angle from separation considerations. This subroutine uses ROOT and ADSTR in the calculation of these angles.

A call to MSSTAR has the form CALL MSSTAR (M, N, VSSTAR), where the elements of the call vector are

M inlet or outlet dimensionless velocity, M_1^* or M_o^* , respectively

N variable switch

VSSTAR Prandtl-Meyer angle from separation criterion, $(\nu_l)_{\min}$ or $(\nu_u)_{\max}$

The other variables used by MSSTAR are

A $\frac{\pi}{4} \left(\sqrt{\frac{\gamma+1}{\gamma-1}} - 1 \right)$

B $\frac{1}{2} \sqrt{\frac{\gamma+1}{\gamma-1}}$

C $\gamma - 1$

D $\gamma + 1$

MS velocity ratio from separation criterion, $(M_l^*)_{\min}$ or $(M_u^*)_{\max}$

X0 see subroutine ROOT

X2 see subroutine ROOT

XINTL see subroutine ROOT

FOFX see subroutine ROOT

SQRDMS $(MS)^2$

Subroutine SIMPS1

This function subprogram is used to perform numerical integration of explicit functions of one variable. The integration is performed by a modification of Simpson's rule, in which a sufficient number of intervals is used to assure six or more significant figures in the result.

A call to SIMPS1 has the form ANSWER = SIMPS1 (XMIN, XMAX, FUNC1, KER), where the elements of the call vector are

XMIN lower limit of integration
 XMAX upper limit of integration
 FUNC1 externally defined function of a single variable
 KER storage for flagging result if necessary
 Other program variables are
 A array for storing functional values at certain partition points
 ANS sum of subapproximations
 B array for storing functional values at certain partition points
 C array for storing functional values at certain partition points
 E array for storing difference terms
 FRAC variable tolerance used for subapproximations
 H distance between successive points of partition
 K variable index
 N counter
 NE equivalent to E
 NTEST equivalent to TEST
 P array for storing successive subapproximations
 Q sum of difference terms
 SIMPS1 value of desired integral
 TEST tester for subapproximations
 T tolerance for difference terms
 V array for storing partition points of interval

Function Subprograms

The following function subprograms are used intermittently throughout the main program and subroutines:

FUNCTION ALFUNC (A, B, Y), defined by ALFUNC where

$$\text{ALFUNC} = \frac{1}{Y} (A - BY^2)^{1/(\gamma-1)}$$

FUNCTION CFACT (Y), defined by CFACT where

$$CFACT = \frac{1}{Y} \left[1 - \left(\frac{K_{\max}^*}{M_l^*} \right)^2 Y^2 \right]^{1/(\gamma-1)}$$

FUNCTION QFACT (Y), defined by QFACT where

$$QFACT = \frac{1}{Y} \left(\frac{\gamma+1}{2} - \frac{\gamma-1}{2} Y^2 \right)^{1/(\gamma-1)}$$

FUNCTION FRAT (Y), defined by FRAT where

$$FRAT = \frac{2\gamma}{Y^{\gamma-1}} \left(\frac{\frac{\gamma+1}{2} - \frac{\gamma-1}{2} Y^2}{\frac{\gamma+1}{2} Y^2 - \frac{\gamma-1}{2}} \right)^{1/(\gamma-1)}$$

FUNCTION FOFRS (X), defined by FOFRS where

$$FOFRS = \sqrt{\frac{\gamma+1}{\gamma-1}} \arcsin \left(\frac{\gamma-1}{X^2} - \gamma \right) + \arcsin \left[(\gamma+1)X^2 - \gamma \right]$$

FUNCTION FKMAX (Y, L), defined by FKMAX where

$$FKMAX = \int_{M_l^*}^{M_u^*} \left[1 - \left(\frac{Y}{M_l^*} \right)^2 Z^2 \right]^{1/(\gamma-1)} \frac{dZ}{Z} + \left[1 - Y^2 \left(\frac{M_u^*}{M_l^*} \right)^2 \right]^{1/(\gamma-1)} - (1 - Y^2)^{1/(\gamma-1)}$$

and L is an optional switch.

FUNCTION ADSTR (X), defined by ADSTR where

$$ADSTR = \sqrt{\frac{\gamma+1}{\gamma-1}} \left\{ 1 - \left[1 - \left(\frac{\gamma-1}{\gamma+1} \right) X^2 \right] \left[1 + \frac{1}{2} \left(\frac{\frac{\gamma}{\gamma+1} X^2}{1 - \frac{\gamma-1}{\gamma+1} X^2} \right) \right]^{(\gamma-1)/\gamma} \right\}^{1/2}$$
